

# IP, ICMP

Dr. Manas Khatua Assistant Professor Dept. of CSE IIT Jodhpur E-mail: <u>manaskhatua@iitj.ac.in</u>

## **Internet's Network Layer**

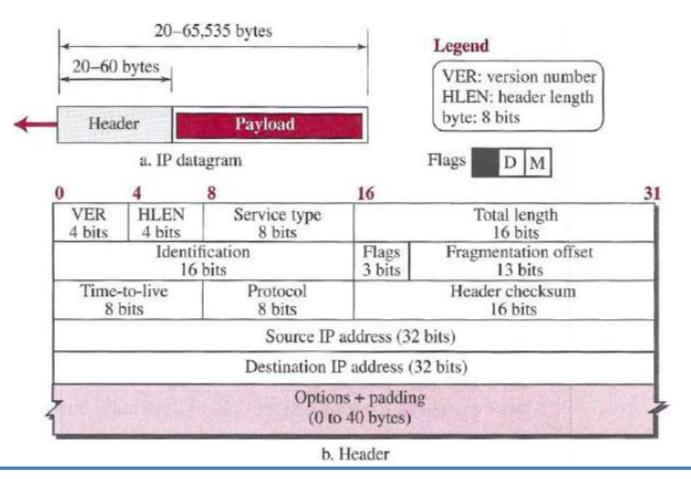

#### Figure 4.12 • A look inside the Internet's network layer

#### **IP Header**

• The most widely used protocol for internetworking is the Internet Protocol (IP).

# **IP Datagram Fields**

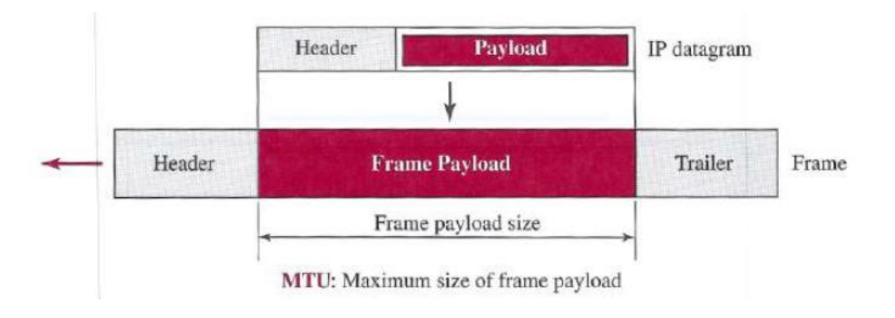

- VER: version of the IPv4 protocol
- HLEN: total length of the datagram header
- ToS: provides *differentiated services* (DiffServ)
- Total length: header plus data in byte
- Identification, Flags, Fragmentation Offset: These three fields are related to the fragmentation of the IP datagram
- TTL: control the maximum number of hops (routers) visited by the datagram
- Protocol: this field helps to define to which protocol the payload should be delivered
- Checksum: helps to check the error in datagram header
- Source & Destination Address: 32 bit IP addresses
- Options & Padding: used for network testing and debugging
- Payload: the packet coming from other protocols that use the service of IP

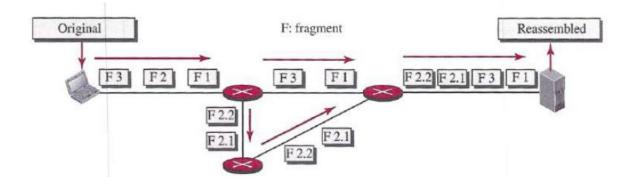

## **Fragmentation & Reassembly**

- A datagram can travel through different networks.
- •
- Each router decapsulates the IP datagram from the frame it receives, processes it, and then encapsulates it in another frame.

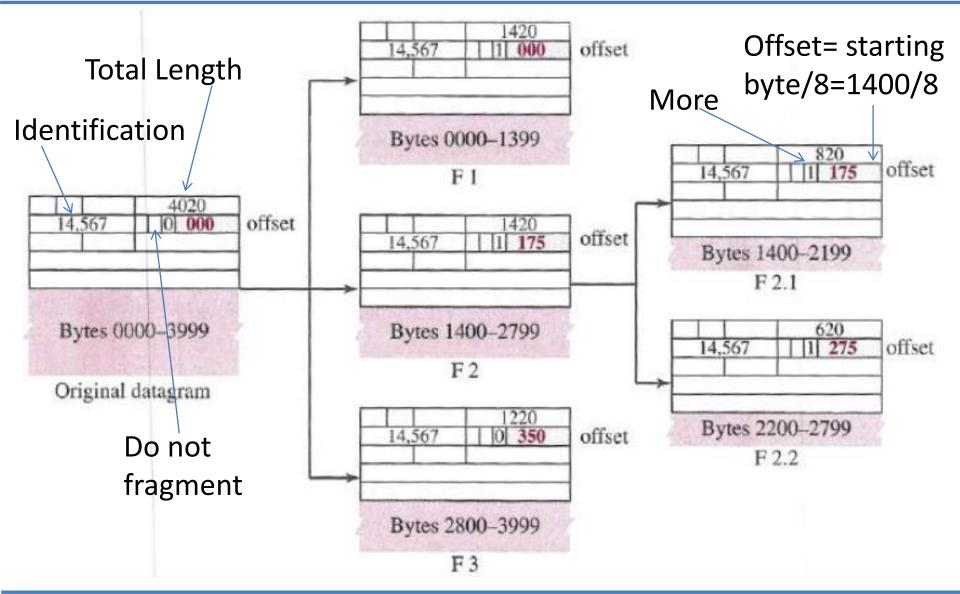

- Fragmentation is done by the source host or intermediate router.
- But, Reassembly is done by the destination host only.
- **16-bit** *identification field*: identifies a datagram. This is the present value of a counter maintained by sender.
- 3-bit flags *field*:
  - Not used,
  - D: do not fragment,
  - M: more fragment
- **13-bit** *fragmentation offset field*: shows the relative position of a fragment w.r.t. the whole datagram

#### **ICMP**

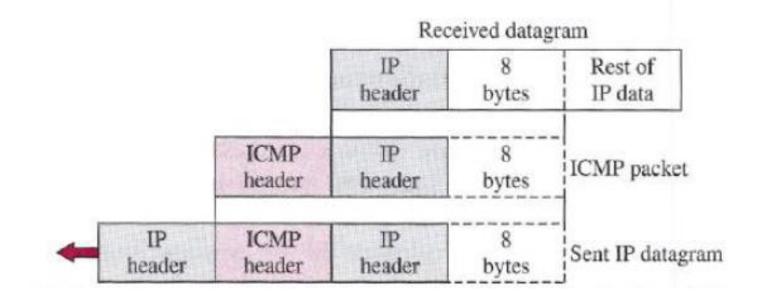

- ICMP: Internet Control Message Protocol
- What happens
  - if something goes wrong?
  - if router discards a datagram?
  - if TTL finishes?
  - if fragmentation is not permitted?
- Need a mechanism for network management

- Its messages are not passed directly to the data-link layer as would be expected.
- Instead, the messages are first encapsulated inside IP datagrams before going to the lower layer.

### **ICMP** Messages

- ICMP Message size:
  - 8-byte header and
  - a variable-size data section

| 8 bits | 8 bits             | 16 bits  |  |  |  |  |  |
|--------|--------------------|----------|--|--|--|--|--|
| Туре   | Code               | Checksum |  |  |  |  |  |
|        | Rest of the header |          |  |  |  |  |  |
|        | Data se            | ction    |  |  |  |  |  |

Error-reporting messages

#### Type and code values

#### Error-reporting messages

- 03: Destination unreachable (codes 0 to 15)
- 04: Source quench (only code 0)
- 05: Redirection (codes 0 to 3)
- 11: Time exceeded (codes 0 and 1)
- 12: Parameter problem (codes 0 and 1)

08 and 00: Echo request and reply (only code 0) 13 and 14: Timestamp request and reply (only code 0)

|            | Data   | section        |  |  |
|------------|--------|----------------|--|--|
| Identifier |        | Sequence numbe |  |  |
| Туре       | Code   | Checksum       |  |  |
| 8 bits     | 8 bits | 16 bits        |  |  |

## **Error Reporting Messages**

- Only error reporting; no error correction
- Messages are sent to original sources of the datagrams
- No error message for:
  - datagram carrying an ICMP error message
  - a fragmented datagram that is not the first fragment
  - a datagram having a multicast address
  - a datagram having a special address such as 127.0.0.0 or 0.0.0.0

- *Ping:* to find if a host is alive and responding
  - The source host sends ICMP echo-request messages;
  - the destination, if alive, responds with ICMP echo-reply messages.
  - It can calculate the round-trip time

| \$ ping auniversity.edu                                  |        |              |
|--|--------|--------------|
| PING auniversity.edu (152.181.8.3) 56 (84) bytes of data | ı.     |              |
| 64 bytes from auniversity.edu (152.181.8.3): icmp_seq=0  | ul=62  | time=1.91 ms |
| 64 bytes from auniversity.edu (152.181.8.3): icmp_seq=1  | ttl=62 | time=2.04 ms |
| 64 bytes from auniversity.edu (152.181.8.3): icmp_seq=2  | ttl=62 | time=1.90 ms |

- The traceroute program in UNIX or tracert in Windows can be used to trace the path of a packet from a source to the destination.
  - It can find the IP addresses of all the routers that are visited along the path
  - It takes help of ICMP error reporting messages

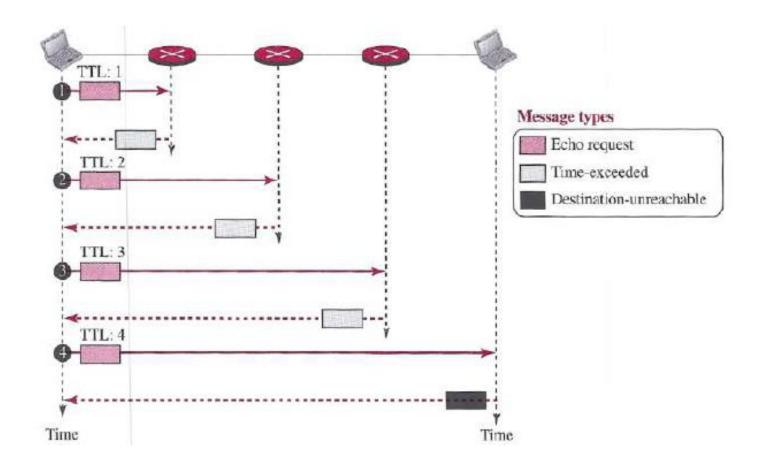

#### \$ traceroute printers.com

traceroute to printers.com (13.1.69.93), 30 hops max, 38-byte packets

| 1 route.front.edu    | (153.18.31.254)  | 0.622 ms | 0.891 ms | 0.875 ms |
|----------------------|------------------|----------|----------|----------|
| 2 ceneric.net        | (137.164.32.140) | 3.069 ms | 2.875 ms | 2.930 ms |
| 3 satire.net         | (132.16.132.20)  | 3.071 ms | 2.876 ms | 2.929 ms |
| 4 alpha.printers.com | (13.1.69.93)     | 5.922 ms | 5.048 ms | 4.922 ms |

• The *traceroute* application program is encapsulated in a UDP user datagram, but *traceroute* intentionally uses a port number that is not available at the destination.

# Thanks!
